CMC and Developability Summary

Project AURORA | A17-03 | Version 1.0 | 4 October 2026 | Illustrative Biologics CMC

All programme details and findings are illustrative. No real company or programme data is included.

Decision relevance

The candidate-nomination question is whether the manufacturing and formulation profile supports IND-enabling development without introducing an avoidable route-of-administration or product-quality risk.

Attribute	Illustrative result	Programme target	Decision interpretation
Freeze-thaw stability	98.2% monomer after 3 cycles	>=97% monomer	Supports current formulation
Viscosity at 150 mg/mL	19 cP	<=15 cP for intended SC route	Challenges intended concentration
Stable-pool titre	3.2 g/L	>=2.5 g/L	Supports process feasibility
Fc glycan profile	Within internal comparator range	Comparator range	No current product-quality signal

Open formulation risk

The concentration-dependent viscosity result is above the illustrative programme target. This does not preclude nomination, but it makes the intended subcutaneous route conditional on a bounded formulation optimisation package.

Required before final nomination

- Complete buffer and excipient screen at 120-160 mg/mL.
- Confirm aggregation and particle profile after simulated shipping and administration stress.
- Record an intravenous fallback route if the high-concentration target is not achieved.
- Agree the decision threshold with Biologics CMC and programme governance.

Human assessment

The evidence supports a feasible manufacturing path. The route-of-administration claim remains conditional and should be carried into the handover record rather than converted into a single developability score.
